

# Graphs

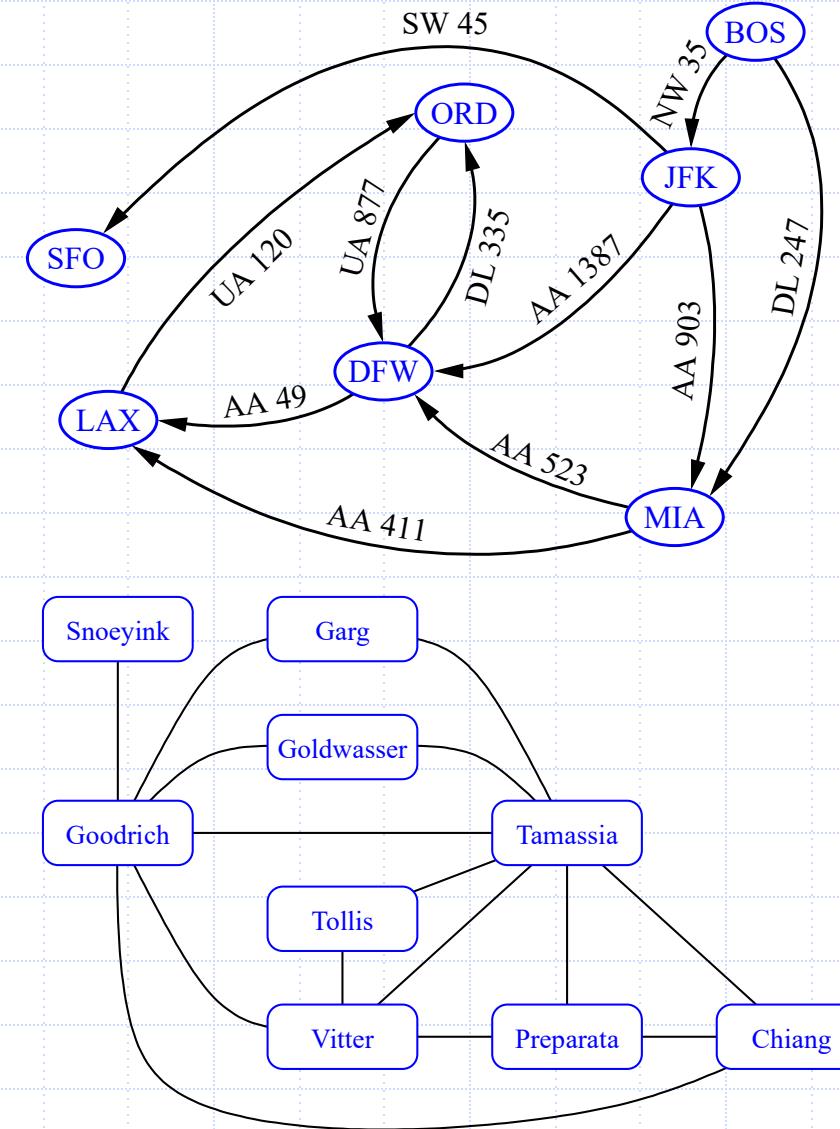

# Graphs

- A graph is a pair  $(V, E)$ , where
  - $V$  is a set of nodes, called **vertices**
  - $E$  is a collection of pairs of vertices, called **edges**
  - Vertices and edges are positions and store elements
- Example:
  - A vertex represents an airport and stores the three-letter airport code
  - An edge represents a flight route between two airports and stores the mileage of the route

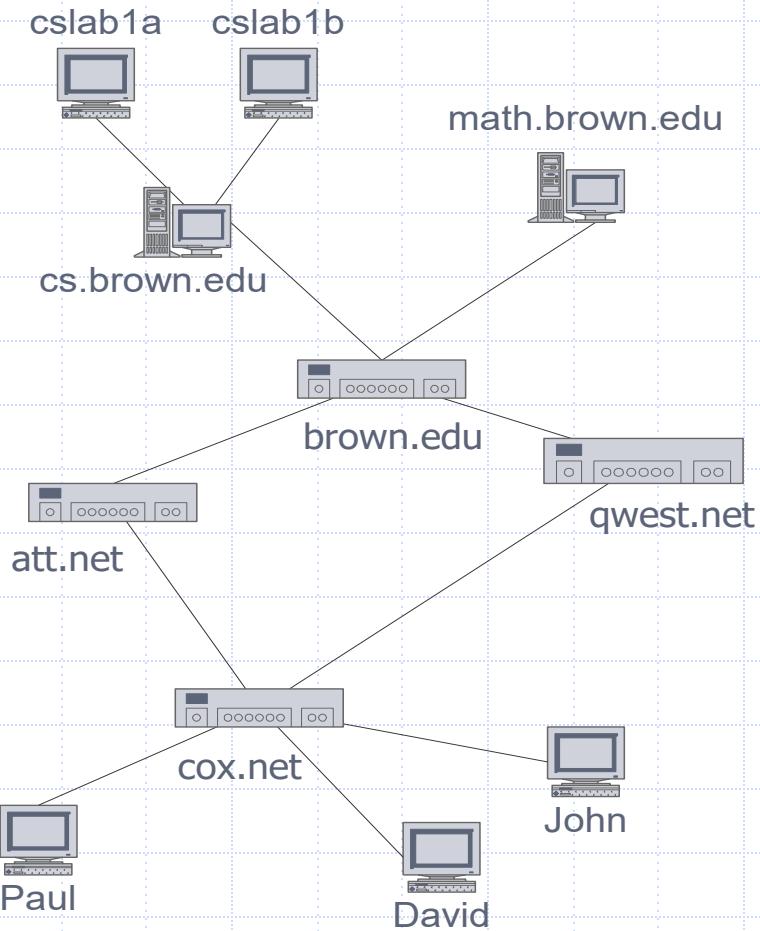

# Edge Types

- Directed edge
  - ordered pair of vertices  $(u, v)$
  - first vertex  $u$  is the origin
  - second vertex  $v$  is the destination
  - e.g., a flight
- Directed graph
  - all the edges are directed
  - e.g., route network
- Undirected edge
  - unordered pair of vertices  $(u, v)$
  - e.g., a flight route
- Undirected graph
  - all the edges are undirected
  - e.g., flight network

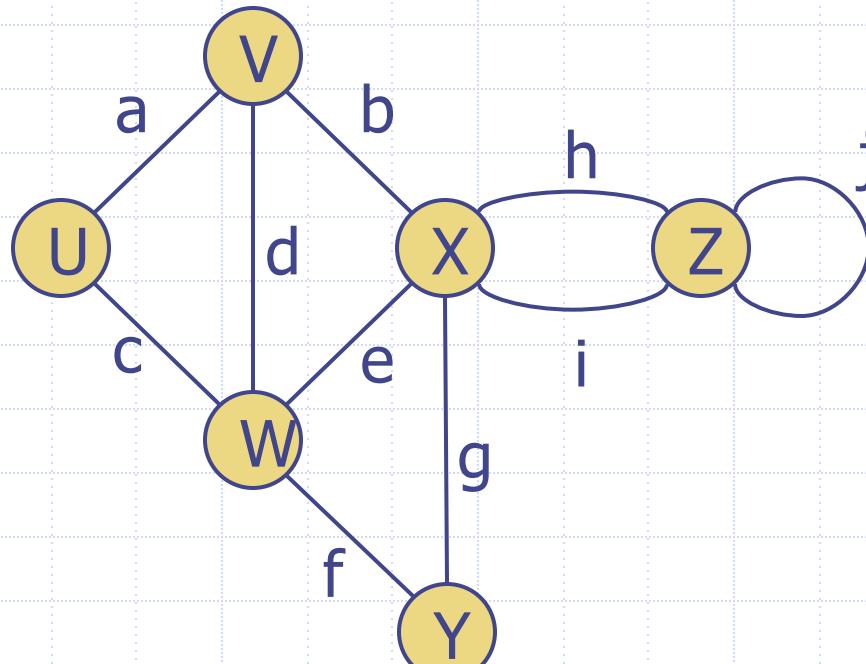

# Applications

- Electronic circuits
  - Printed circuit board
  - Integrated circuit
- Transportation networks
  - Highway network
  - Flight network
- Computer networks
  - Local area network
  - Internet
  - Web
- Databases
  - Entity-relationship diagram

# Terminology

- End vertices (or endpoints) of an edge
  - U and V are the endpoints of a
- Edges incident on a vertex
  - a, d, and b are incident on V
  - outgoing edges
  - incoming edges
- Adjacent vertices
  - U and V are adjacent
- Degree of a vertex
  - X has degree 5
  - in-degree
  - out-degree
- Parallel edges
  - h and i are parallel edges
- Self-loop
  - j is a self-loop

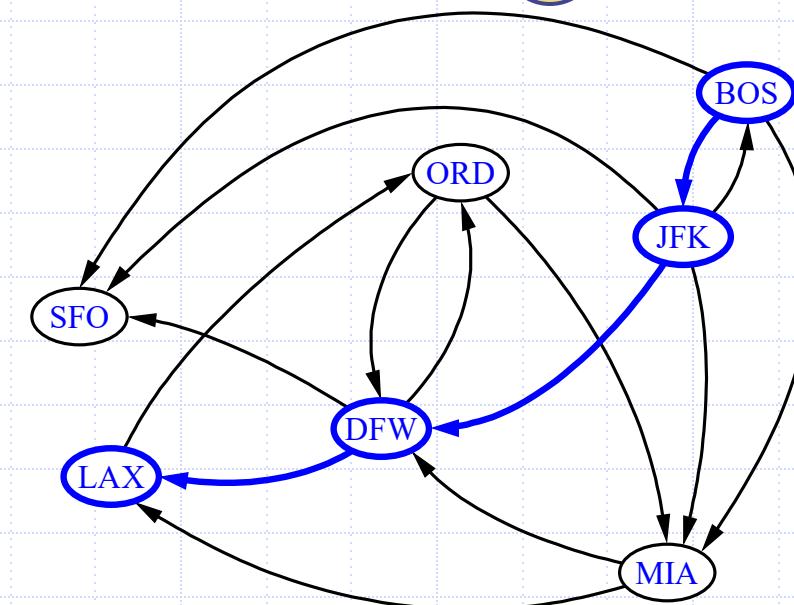

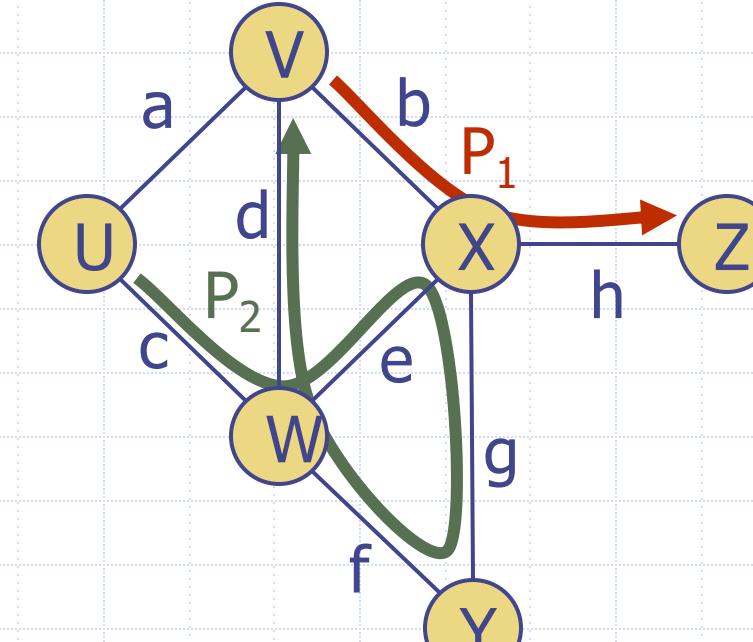

# Question

- What is the sum of degrees of all vertices?

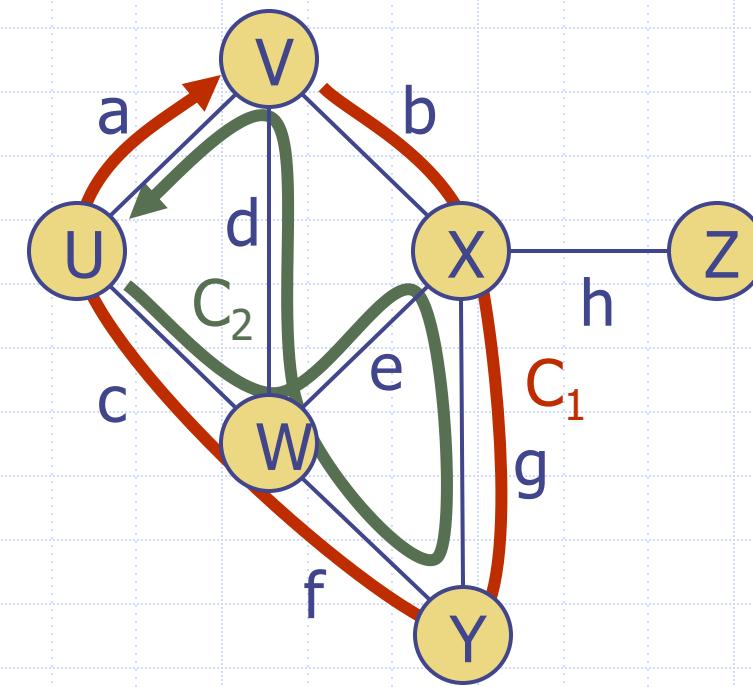

# Terminology (2)

- Path
  - sequence of alternating vertices and edges
  - begins with a vertex
  - ends with a vertex
  - each edge is preceded and followed by its endpoints
- Simple path
  - path such that all its vertices and edges are distinct
- Examples
  - $P_1=(V,b,X,h,Z)$  is a simple path
  - $P_2=(U,c,W,e,X,g,Y,f,W,d,V)$  is a path that is not simple

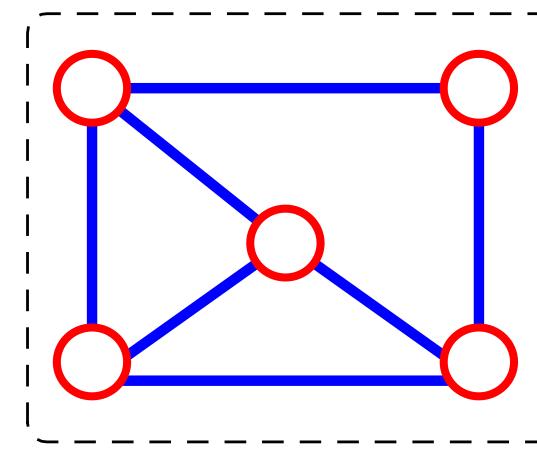

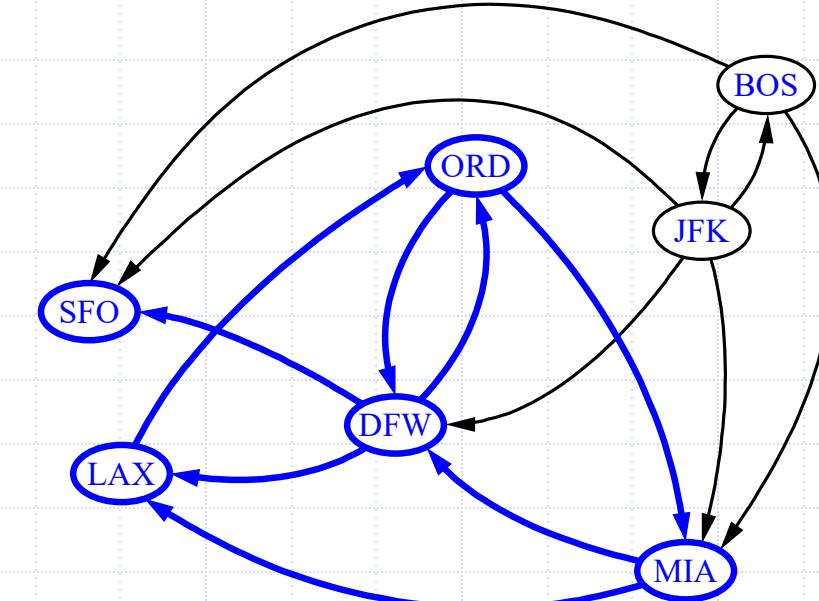

# Terminology (3)

- Cycle
  - circular sequence of alternating vertices and edges
  - each edge is preceded and followed by its endpoints
- Simple cycle
  - cycle such that all its vertices and edges are distinct
- Examples
  - $C_1 = (V, b, X, g, Y, f, W, c, U, a, \leftarrow)$  is a simple cycle
  - $C_2 = (U, c, W, e, X, g, Y, f, W, d, V, a, \leftarrow)$  is a cycle that is not simple

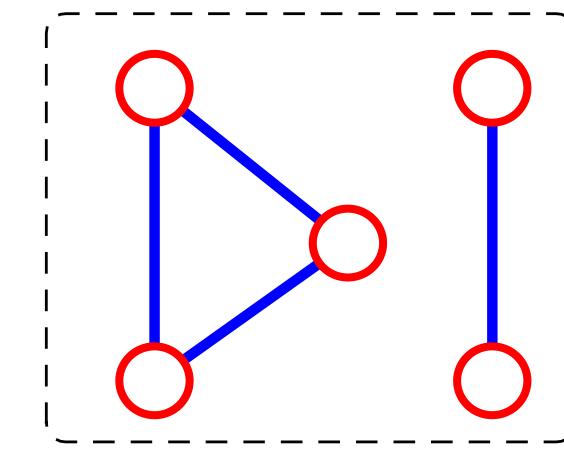

# Terminology (4)

- ❑ Reachable
  - $V$  is reachable from  $U$  if there is a path from  $U$  to  $V$ .
  - Undirected graph – reachability is symmetric
- ❑ Connected
  - a graph is connected if, for any two vertices, there is a path between them
- ❑ subgraph
  - subset of vertices and edges forming a graph

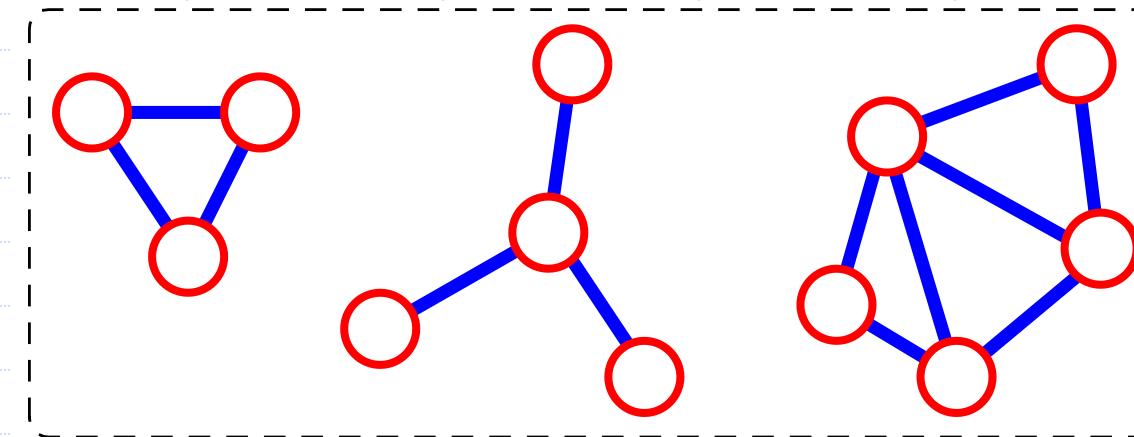

connected

not connected

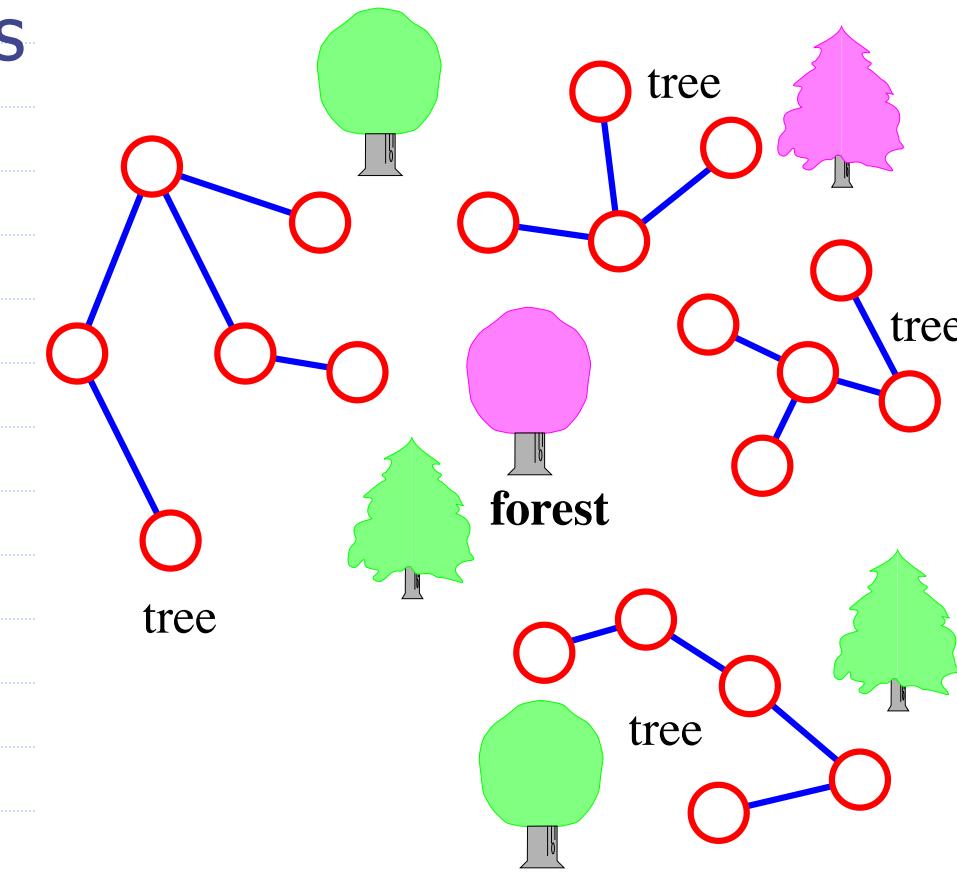

# Terminology (5)

- Connected Component: maximal connected subgraph, e.g., the graph below has 3 connected components.

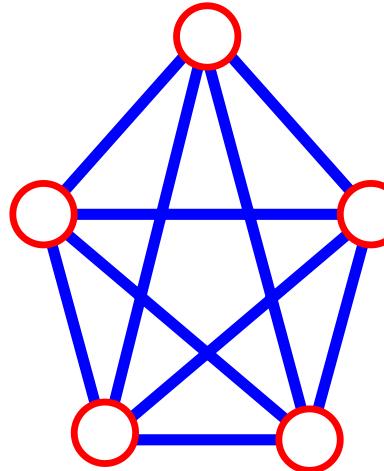

# Terminology (6)

- Tree – connected graph without cycles
  - free tree
- Forest – collection of trees

# Connectivity

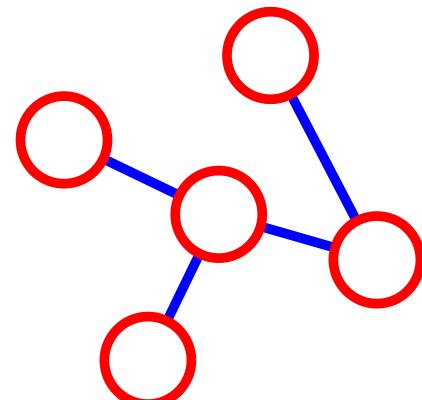

- Let
  - $n$  = # of vertices
  - $m$  = # of edges
- Complete graph – all pairs of vertices are adjacent
  - There are  $n(n-1)/2$  pairs of vertices and so  $m=n(n-1)/2$
- If a graph is not complete,  $m < n(n-1)/2$

$$\begin{aligned}n &= 5 \\m &= (5 * 4)/2 = 10\end{aligned}$$

# Connectivity (2)

- $n = \# \text{vertices}$
- $m = \# \text{edges}$
- For a tree  $m = n - 1$

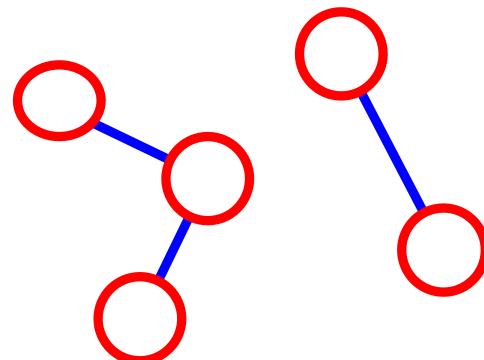

$$\begin{aligned} n &= 5 \\ m &= 4 \end{aligned}$$

- Prove!
  - Tree – connected graph without cycles

# Connectivity (3)

- $n = \# \text{vertices}$
- $m = \# \text{edges}$
- For a tree  $m = n - 1$
- If  $m < n - 1$ ,  $G$  is not connected

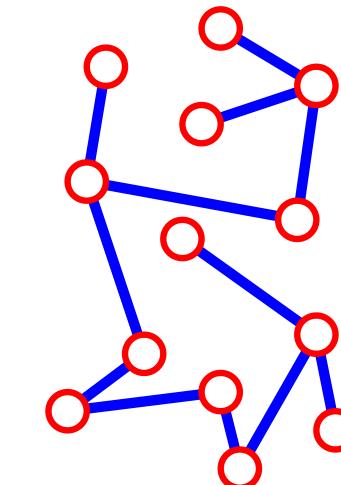

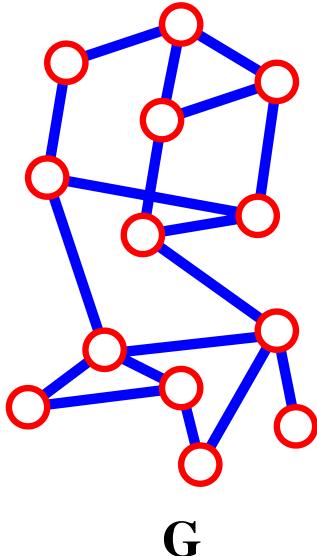

$$\begin{aligned} n &= 5 \\ m &= 3 \end{aligned}$$

- Prove

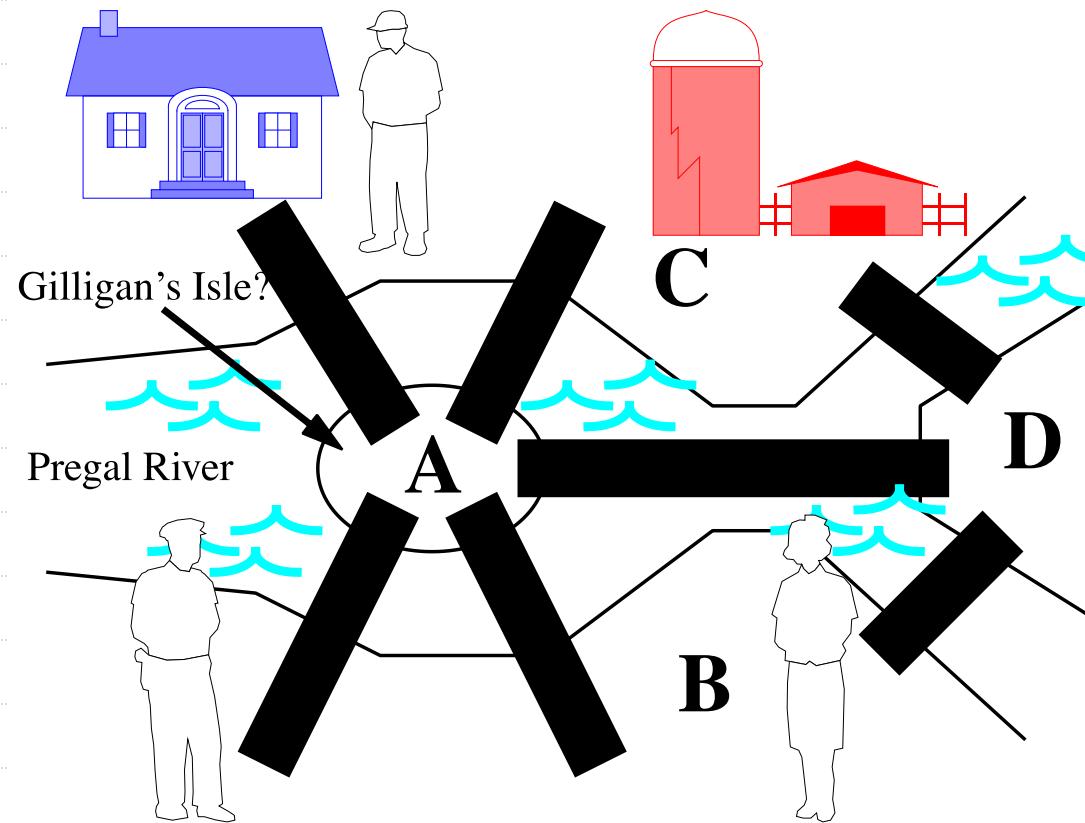

# Spanning Tree

- A spanning tree of  $G$  is a subgraph which
  - is a tree
  - contains all vertices of  $G$

- Failure of any edge disconnects system

# Euler and the Koenigsberg Bridges

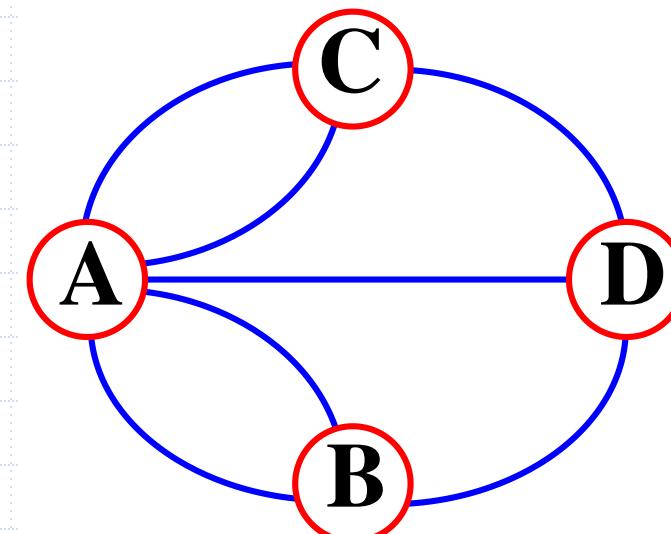

Can one walk across each bridge exactly once and return at the starting point?

In 1736, Euler proved that this is not possible.

# Graph Model (with parallel edges)

- Eulerian Tour- path that traverses every edge exactly once and returns to the first vertex
- Euler's Theorem – A graph has a Eulerian tour if and only if all vertices have even degree

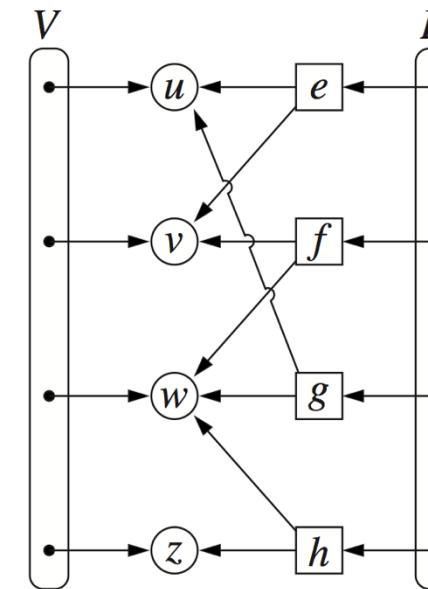

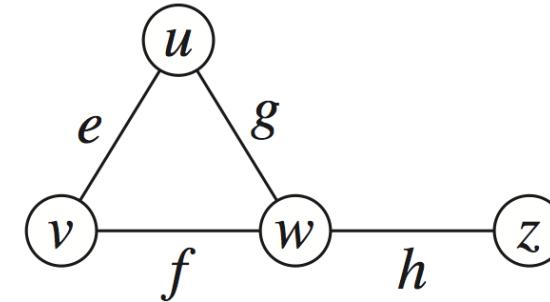

# Vertices and Edges

- A **graph** is a collection of **vertices** and **edges**.
- We model the abstraction as a combination of three data types: **Vertex**, **Edge**, and **Graph**.
- A **Vertex** is a lightweight object that stores an arbitrary element provided by the user (e.g., an airport code)
  - We assume it supports a method, `element()`, to retrieve the stored element.
- An **Edge** stores an associated object (e.g., a flight number, travel distance, cost), retrieved with the `element( )` method.

# Edge List Structure

- ❑ Vertex object
  - element
  - reference to position in vertex sequence
- ❑ Edge object
  - element
  - origin vertex object
  - destination vertex object
  - reference to position in edge sequence
- ❑ Vertex sequence
  - sequence of vertex objects
- ❑ Edge sequence
  - sequence of edge objects

# Performance

- $n$  vertices,  $m$  edges
- no parallel edges
- no self-loops

# Adjacency Matrix Structure

- Edge list structure
- Augmented vertex objects
  - Integer key (index) associated with vertex
- 2D-array adjacency array
  - Reference to edge object for adjacent vertices
  - Null for non adjacent vertices
- The “old fashioned” version just has 0 for no edge and 1 for edge

	0	1	2	3
u	→	0		
v	→	1		
w	→	2		
z	→	3		

Diagram illustrating the mapping of vertices to indices (0, 1, 2, 3) and the corresponding 4x4 adjacency matrix. The matrix rows are indexed by vertices u, v, w, and z, and the columns are indexed by vertices u, v, w, and z. The matrix entries are labeled with edges: e (u,v), f (v,w), g (u,w), h (w,z), and i (x,y). The matrix is as follows:

	e	g	
e		f	
g	f		h
		h

# Graph Search Algorithms

- Systematic search of every edge and vertex of the graph
- Graph  $G = (V, E)$  is either directed or undirected
- Applications
  - Compilers
  - Networks
  - Graphics
  - Gaming

# Breadth-First Search

# Breadth-First Search

- ❑ Breadth-first search (BFS) is a general technique for traversing a graph
- ❑ A BFS traversal of a graph  $G$ 
  - Visits all the vertices and edges of  $G$
  - Determines whether  $G$  is connected
  - Computes the connected components of  $G$
  - Computes a spanning forest of  $G$
- ❑ BFS on a graph with  $n$  vertices and  $m$  edges takes  $O(n + m)$  time
- ❑ BFS can be further extended to solve other graph problems
  - Find and report a path with the minimum number of edges between two given vertices

# BFS Algorithm

- The algorithm uses a mechanism for setting and getting “labels” of vertices and edges

## Algorithm $BFS(G)$

**Input** graph  $G$

**Output** labeling of the edges  
and partition of the  
vertices of  $G$

```
for all  $u \in G.vertices()$   
    setLabel( $u$ , UNEXPLORED)  
for all  $e \in G.edges()$   
    setLabel( $e$ , UNEXPLORED)  
for all  $v \in G.vertices()$   
    if getLabel( $v$ ) = UNEXPLORED  
        BFS( $G, v$ )
```

## Algorithm $BFS(G, s)$

```
 $L_0 \leftarrow$  new empty sequence  
 $L_0.addLast(s)$   
setLabel( $s$ , VISITED)  
 $i \leftarrow 0$   
while  $\neg L_i.isEmpty()$   
     $L_{i+1} \leftarrow$  new empty sequence  
    for all  $v \in L_i.elements()$   
        for all  $e \in G.incidentEdges(v)$   
            if getLabel( $e$ ) = UNEXPLORED  
                 $w \leftarrow$  opposite( $v, e$ )  
                if getLabel( $w$ ) = UNEXPLORED  
                    setLabel( $e$ , DISCOVERY)  
                    setLabel( $w$ , VISITED)  
                     $L_{i+1}.addLast(w)$   
                else  
                    setLabel( $e$ , CROSS)  
 $i \leftarrow i + 1$ 
```

# BFS - Example

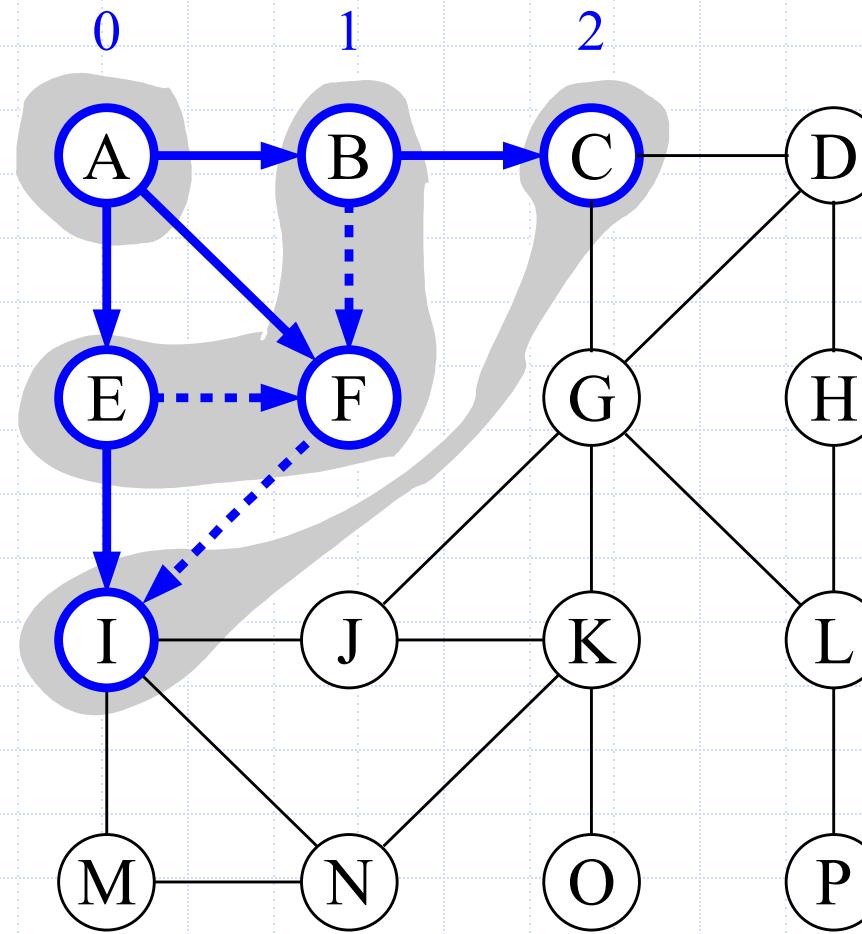

Breadth First Search

# BFS - Example

# BFS - Example

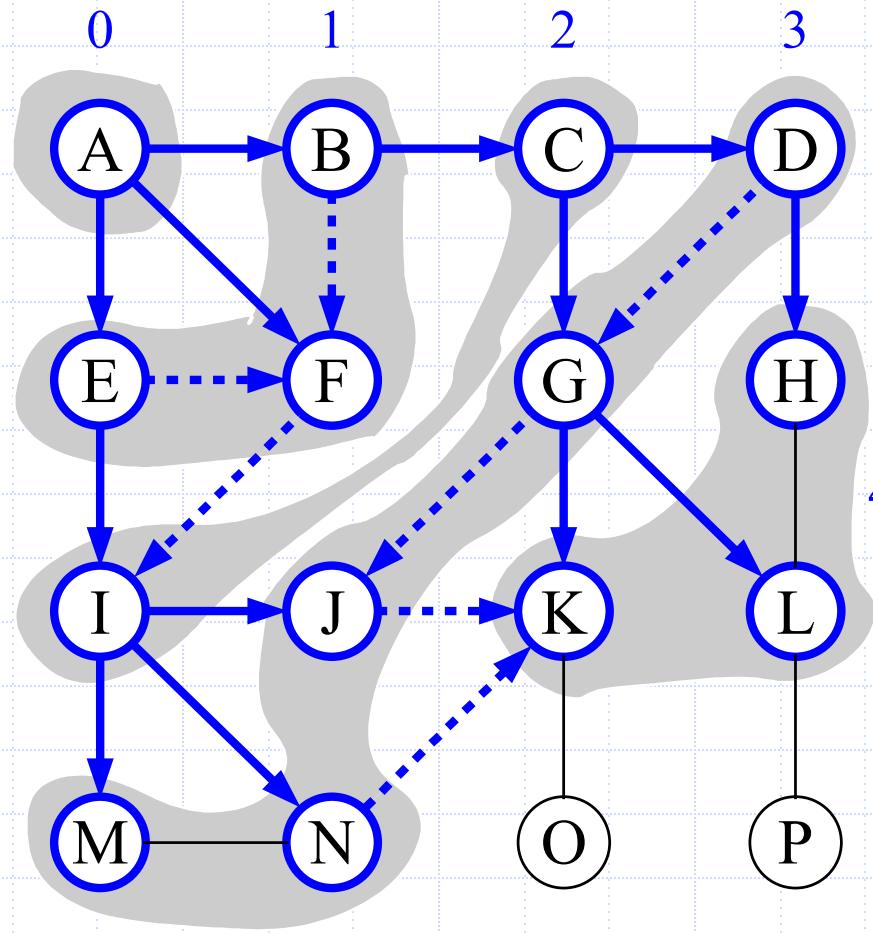

Breadth First Search

# BFS - Example

# Analysis

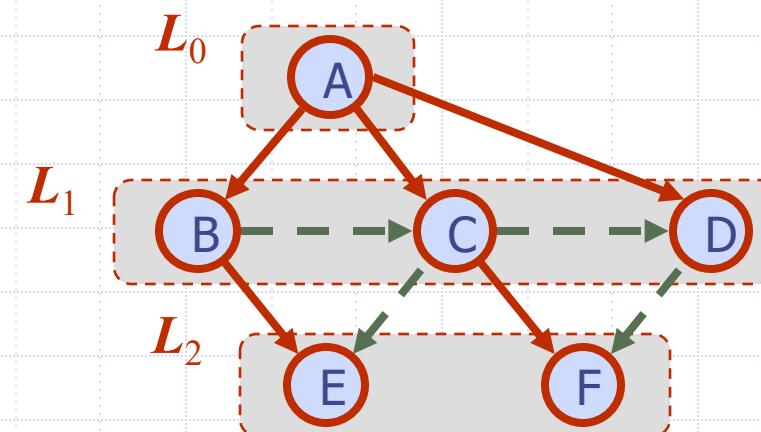

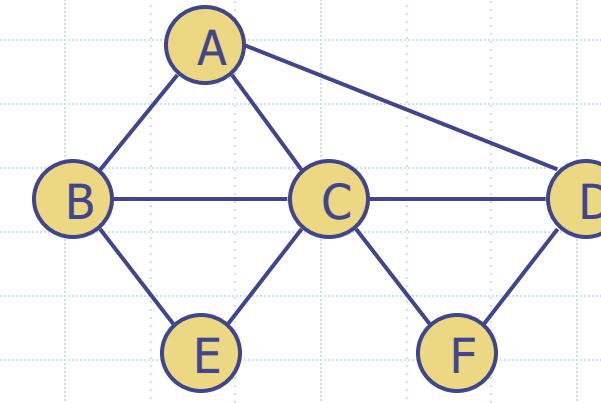

- Setting/getting a vertex/edge label takes  $O(1)$  time
- Each vertex is labeled twice
  - once as UNEXPLORED
  - once as VISITED
- Each edge is labeled twice
  - once as UNEXPLORED
  - once as DISCOVERY or CROSS
- Each vertex is inserted once into a sequence  $L_i$
- Method `incidentEdges` is called once for each vertex
- BFS runs in  $O(n + m)$  time provided the graph is represented by the adjacency list structure
  - Recall that  $\sum_v \deg(v) = 2m$

# Properties

## Notation

$G_s$ : connected component of  $s$

- $G_s$  is a breadth first tree
  - $V_s$  consists of the vertices reachable from  $s$ , and
  - for all  $v$  in  $V_s$  there is a unique simple path from  $s$  to  $v$  in  $G_s$  that is also a shortest path from  $s$  to  $v$  in  $G$
- The edges in  $G_s$  are called tree edges
- For every vertex  $v$  reachable from  $s$ , the path in the breadth first tree from  $s$  to  $v$ , corresponds to a shortest path in  $G$

# Properties (2)

## Notation

$G_s$ : connected component of  $s$

## Property 1

$BFS(G, s)$  visits all the vertices and edges of  $G_s$

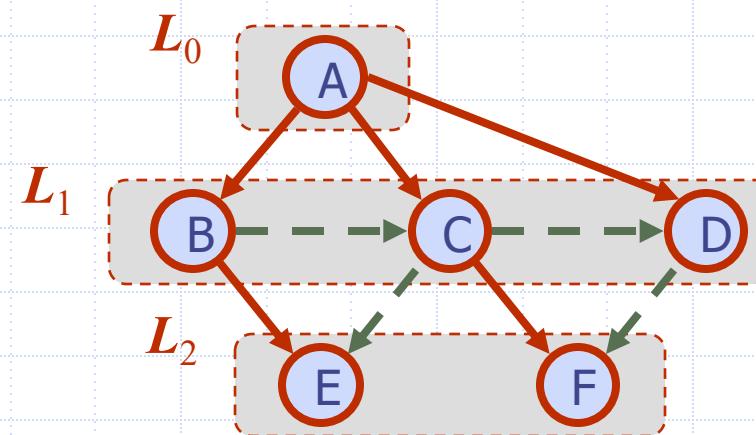

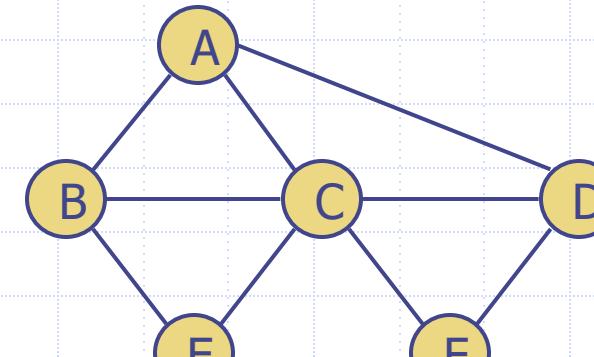

## Property 2

The discovery edges labeled by  $BFS(G, s)$  form a spanning tree  $T_s$  of  $G_s$

## Property 3

For each vertex  $v$  in  $L_i$

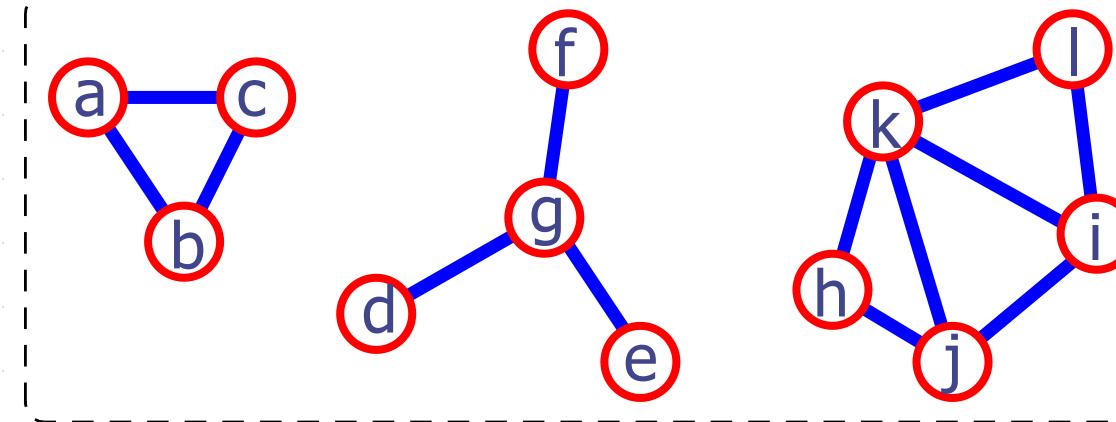

- The path of  $T_s$  from  $s$  to  $v$  has  $i$  edges
- Every path from  $s$  to  $v$  in  $G_s$  has at least  $i$  edges

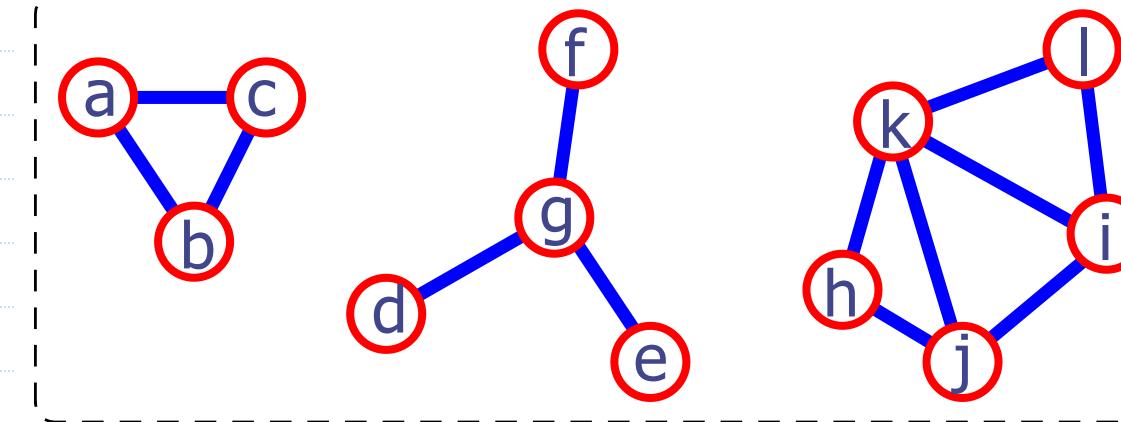

# Applications

- We can specialize the BFS traversal of a graph  $G$  to solve the following problems in  $O(n + m)$  time
  - Compute the connected components of  $G$
  - Compute a spanning forest of  $G$
  - Given two vertices of  $G$ , find a path in  $G$  between them with the minimum number of edges, or report that no such path exists
  - Check if a connected graph  $G$  is bipartite.

# Applications – Computing Connected Components

# Applications – Computing Spanning Forest

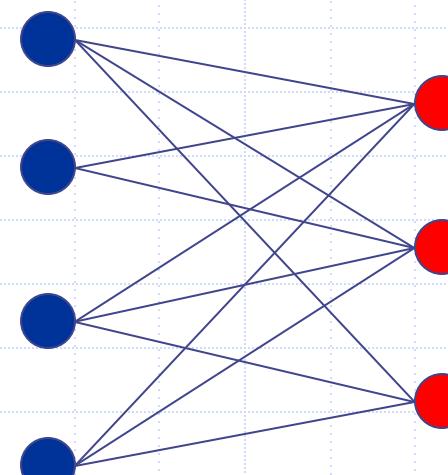

# Applications – Shortest Path between two nodes

- In a BFS starting from a vertex  $v$ , the level number of vertex  $u$  is the length of the shortest path from  $v$  to  $u$ .
- Proof
  - show there is a path from  $v$  to  $u$ .
  - a path of smaller length will jump a level
    - ◆ violating the BFS.

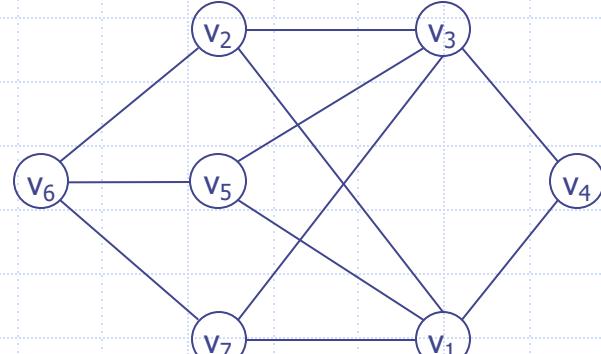

# Applications – Check if a graph is bipartite

- An undirected graph  $G = (V, E)$  is **bipartite** if the nodes can be colored red or blue such that every edge has one red and one blue end.

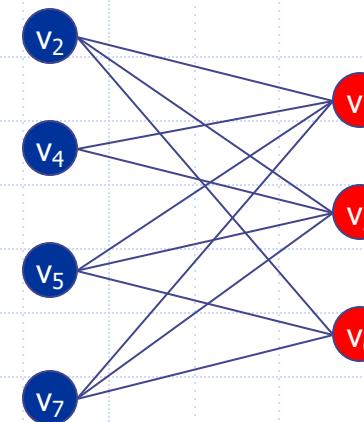

# Testing Bipartiteness

- Given a graph  $G$ , is it bipartite?
- Before attempting to design an algorithm, we need to understand structure of bipartite graphs.

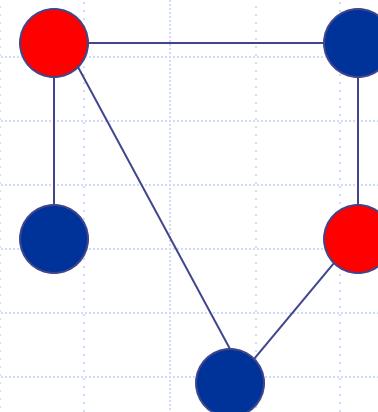

a bipartite graph  $G$

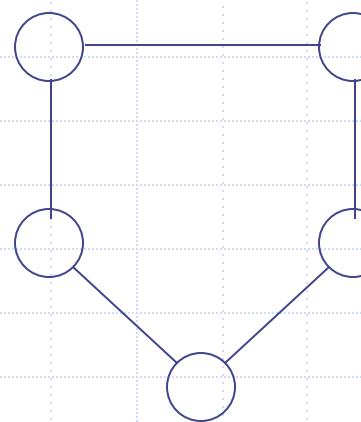

another drawing of  $G$

# Preliminary

- Lemma. If  $G$  has an odd cycle, then it cannot be bipartite.
- Proof: Not possible to 2-color the odd cycle, let alone  $G$ .

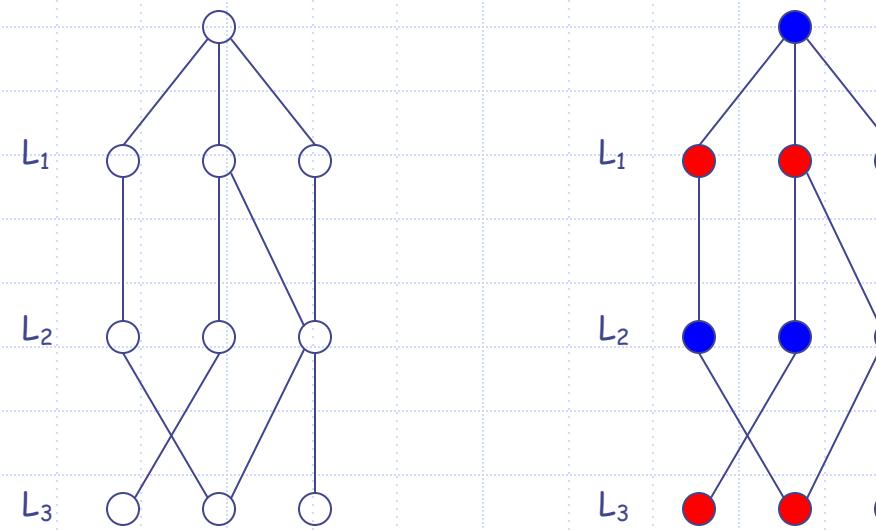

bipartite  
(2-colorable)

not bipartite  
(not 2-colorable)

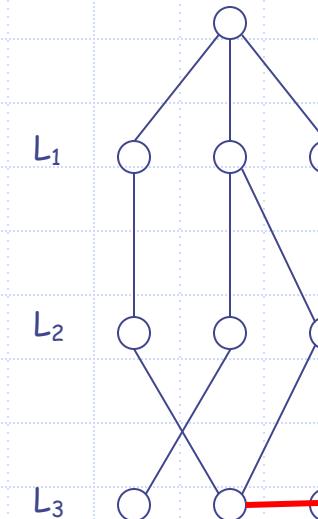

# Bipartiteness and BFS

- Lemma. Let  $G$  be a connected graph, and let  $L_0, \dots, L_k$  be the layers produced by BFS starting at node  $s$ . Exactly one of the following holds.
  - case 1: No edge of  $G$  joins two nodes of the same layer, and  $G$  is bipartite.

# Bipartiteness and BFS

- Lemma. Let  $G$  be a connected graph, and let  $L_0, \dots, L_k$  be the layers produced by BFS starting at node  $s$ . Exactly one of the following holds.
  - case 1: No edge of  $G$  joins two nodes of the same layer, and  $G$  is bipartite.
  - case 2: An edge of  $G$  joins two nodes of the same layer, and  $G$  contains an odd-length cycle (and hence is not bipartite).

# Bipartiteness and BFS

- Lemma. Let  $G$  be a connected graph, and let  $L_0, \dots, L_k$  be the layers produced by BFS starting at node  $s$ . Exactly one of the following holds.
  - case 1: No edge of  $G$  joins two nodes of the same layer, and  $G$  is bipartite.
  - case 2: An edge of  $G$  joins two nodes of the same layer, and  $G$  contains an odd-length cycle (and hence is not bipartite).
- Proof case 2:
  - Suppose  $(x, y)$  is an edge with  $x, y$  in the same level  $L_j$ .
  - Let  $z = \text{LCA}(x, y)$  – lowest common ancestor
  - Let  $L_i$  be the level containing  $z$
  - Consider the cycle that takes edge from  $x$  to  $y$ , then the path from  $y$  to  $x$ , then  $z$  to  $x$
  - The length of this path is  $1 + (j - i) + (j - i)$ , which is odd

# Question

- If  $G$  has only even length cycles, then  $G$  is bipartite.
